Abstract

We introduce invariants of graphs embedded in S^3 which are related to the Wu invariant and the Simon invariant. Then we use our invariants to prove that certain graphs are intrinsically chiral, and to obtain lower bounds for the minimal crossing number of particular embeddings of graphs in S^3 .

1. Introduction

While there are numerous invariants for embeddings of graphs in 3-manifolds, most have limited applications either because they are hard to compute or because they are only defined for particular types of graphs. For example, Thompson [18] defined a powerful polynomial invariant for graphs embedded in arbitrary 3-manifolds, which can detect whether an embedding of a graph in S^3 is planar. However, computing Thompson's invariant requires identifying topological features of a sequence of 3-manifolds, such as whether each manifold is compressible.

Yamada [21] and Yokota [22] introduced polynomial invariants for spatial graphs (i.e., graphs embedded in S^3). The Yamada polynomial is an ambient isotopy invariant for spatial graphs with vertices of degree at most 3. However, for other spatial graphs it is only a regular isotopy invariant. It is convenient to use because it can be computed using skein relations. Also, the Yamada polynomial can be used to detect whether a spatial graph with vertices of degree at most 3 is chiral (i.e., distinct from its mirror image). The Yokota polynomial is an

Fig. 1. Achiral embeddings of K_5 and $K_{3,3}$.

ambient isotopy invariant for all spatial graphs that reduces to the Yamada polynomial for graphs with vertices of degree at most 3. However, the Yokota polynomial is more difficult to compute, and cannot be used to show that a spatial graph is chiral.

In a lecture in 1990, Jon Simon introduced an invariant of embeddings of the graphs K_5 and $K_{3,3}$ with labeled vertices in S^3 . The Simon invariant is easy to compute from a projection of an embedding and has been useful in obtaining results about embeddings of non-planar graphs [5, 8–10, 12–14, 16, 17]. In 1995, Taniyama [17] showed that the Simon invariant is a special case of a cohomology invariant for all spatial graphs which had been introduced by Wu [19, 20], and showed that the Wu invariant can be defined combinatorially from a graph projection. However, the Wu invariant is not always easy to compute, and (like the Simon invariant) depends on the choice of labeling of the vertices of a graph. For this reason, the role of the Wu invariant in distinguishing a spatial graph from its mirror image has been limited to showing that for any embedded non-planar graph Γ , there is no orientation reversing homeomorphism of (S^3, Γ) that fixes every vertex of Γ (see [8]). Without this restriction on the vertices, many non-planar graphs including K_5 and $K_{3,3}$ have achiral embeddings as shown in Figure 1.

In this paper, we define numerical invariants that are obtained by reducing the Wu invariant and by generalizing the Simon invariant. We then use our invariants to prove that no matter how the complete graph K_7 , the Möbius ladders M_{2N+1} , and the Heawood graph are embedded in S^3 , there is no orientation reversing homeomorphism of S^3 which takes the embedded graph to itself. Finally, we show that our invariants can be used to give a lower bound on the minimal crossing number of embedded graphs.

2. Wu invariants and reduced Wu invariants

In 1960, Wu [19] introduced an invariant as follows. Let $C_2(X)$ be the *configuration space* of ordered pairs of points from a topological space X, namely

$$C_2(X) = \{(x, y) \in X \times X \mid x \neq y\}.$$

Let σ be the involution of $C_2(X)$ given by $\sigma(x, y) = (y, x)$. The integral cohomology group of Ker $(1 + \sigma_{\sharp})$ denoted by $H^*(C_2(X), \sigma)$ is said to be the *skew-symmetric integral cohomology group* of the pair $(C_2(X), \sigma)$, where σ_{\sharp} denotes the chain map induced by σ . Wu [19] proved that $H^2(C_2(\mathbb{R}^3), \sigma) \cong \mathbb{Z}$, and hence is generated by some element Σ . Let $f : G \to \mathbb{R}^3$ be a spatial embedding of a graph G with labeled vertices and orientations on the edges. Then f naturally induces an equivariant embedding $f \times f : C_2(G) \to C_2(\mathbb{R}^3)$ with respect to the action σ , and therefore induces a homomorphism

$$(f \times f)^* : H^2(C_2(\mathbb{R}^3), \sigma) \longrightarrow H^2(C_2(G), \sigma).$$

The element $(f \times f)^*(\Sigma)$ is an ambient isotopy invariant known as the *Wu invariant*.

Fig. 2. The Wu invariants for embeddings of these graphs are given in Examples 2.1, 2.2 and 2.3.

In order to explicitly calculate the Wu invariant, Taniyama [17] developed the following combinatorial approach. Let G be a graph with vertices labeled v_1, v_2, \ldots, v_m and oriented edges labeled e_1, e_2, \ldots, e_n . For each pair of disjoint edges e_i and e_j , we define a variable $E^{e_i,e_j} = E^{e_j,e_i}$; and for each edge e_i and vertex v_s which is disjoint from e_i , we define a variable V^{e_i,v_s} . Let Z(G) be the free \mathbb{Z} -module generated by the collection of E^{e_i,e_j} 's. For each V^{e_i,v_s} , let $\delta(V^{e_i,v_s})$ be the element of Z(G) given by the sum of all E^{e_i,e_k} such that e_k is disjoint from e_i and has initial vertex v_s , minus the sum of all E^{e_i,e_k} such that e_k is disjoint from e_i and has terminal vertex v_s . Thus

$$\delta(V^{e_i,v_s}) = \sum_{\substack{I(k)=s\\e_i\cap e_k = \emptyset}} E^{e_i,e_k} - \sum_{\substack{T(l)=s\\e_i\cap e_l = \emptyset}} E^{e_i,e_l},$$

where I(k) = s indicates that the initial vertex of e_k is v_s , and T(l) = s indicates that the terminal vertex of e_l is v_s . Let B(G) be the submodule of Z(G) generated by the collection of $\delta(V^{e_l,v_s})$'s. We let L(G) denote the quotient module Z(G)/B(G), and call it a *linking module* of G. Then $L(G) \cong H^2(C_2(G), \sigma)$.

Now let f be an embedding of the labeled oriented graph G in S^3 . Fix a projection of f(G) and let $\ell(f(e_i), f(e_j)) = \ell(f(e_j), f(e_i))$ denote the sum of the signs of the crossings between $f(e_i)$ and $f(e_j)$. Taniyama [17] showed that the equivalence class

$$\mathcal{L}(f) = \left[\sum_{e_i \cap e_j = \emptyset} \ell(f(e_i), f(e_j)) E^{e_i, e_j}\right] \in L(G)$$

coincides with $(f \times f)^*(\Sigma)$ through the isomorphism from $H^2(C_2(G), \sigma)$ to L(G). Thus we may regard $\mathcal{L}(f)$ as the Wu invariant of f. Furthermore, $H^2(C_2(G), \sigma)$ is torsion free, namely L(G) is a free \mathbb{Z} -module, and for an orientation-reversing self-homeomorphism Φ of S^3 , it follows that $\mathcal{L}(\Phi \circ f) = -\mathcal{L}(f)$.

Example 2·1. Let $2K_3$ denote the graph consisting of two copies of K_3 , labeled and oriented as illustrated in Figure 2, and let f be a spatial embedding of $2K_3$. It was shown in [17] that the linking module $L(2K_3) = \langle [E^{e_1,d_1}] \rangle \cong \mathbb{Z}$, and the Wu invariant of f is given by:

$$\mathcal{L}(f) = \sum_{1 \leq i, j \leq 3} \ell(f(e_i), f(d_j))[E^{e_1, d_1}] = 2\mathrm{lk}(f)[E^{e_1, d_1}],$$

where lk(f) denotes the *linking number* of the pair of triangles in S^3 .

Example 2.2. Let K_5 denote the complete graph on five vertices, labelled and oriented as illustrated in Figure 2, and let f be a spatial embedding of K_5 . It was shown in [17] that the

524 E. FLAPAN, W.R. FLETCHER AND R. NIKKUNI

linking module $L(K_5) = \langle [E^{e_1, e_3}] \rangle \cong \mathbb{Z}$ and the Wu invariant is given by:

$$\mathcal{L}(f) = \sum_{a \cap b = \emptyset} \varepsilon(a, b) \ell(f(a), f(b))[E^{e_1, e_3}],$$

where $\varepsilon(a, b)$ is defined by $\varepsilon(e_i, e_j) = 1$, $\varepsilon(d_i, d_j) = -1$ and $\varepsilon(e_i, d_j) = -1$.

We work out the following example which it is given in [17] without details.

Example 2.3. Let $K_{3,3}$ denote the complete bipartite graph, labelled and oriented as illustrated in Figure 2, and let f be a spatial embedding of $K_{3,3}$. Then $Z(K_{3,3})$ is a free \mathbb{Z} -module generated by

$$E^{c_1,c_3}, E^{c_2,c_4}, E^{c_3,c_5}, E^{c_4,c_6}, E^{c_5,c_1}, E^{c_6,c_2}, E^{c_1,c_4}, E^{c_2,c_5}, E^{c_3,c_6}, E^{b_1,c_2}, E^{b_1,c_5}, E^{b_3,c_4}, E^{b_3,c_1}, E^{b_2,c_3}, E^{b_2,c_6}, E^{b_1,b_2}, E^{b_2,b_3}, E^{b_3,b_1}$$

and $B(K_{3,3})$ is a submodule of $Z(K_{3,3})$ generated by

$$\begin{split} E^{b_1,c_2} &= E^{c_6,c_2}, \ E^{c_1,c_3} - E^{c_3,c_6}, \ E^{c_1,c_4} - E^{c_4,c_6}, \\ E^{c_5,c_1} &+ E^{b_1,c_5}, \ E^{b_3,c_1} + E^{b_3,b_1}, \ E^{b_1,b_2} - E^{b_2,c_6}, \\ &- E^{b_2,c_3} - E^{c_1,c_3}, \ E^{c_2,c_4} - E^{c_1,c_4}, \ E^{c_2,c_5} - E^{c_5,c_1}, \\ E^{c_6,c_2} - E^{b_2,c_6}, \ - E^{b_2,b_3} - E^{b_3,c_1}, \ E^{b_1,c_2} - E^{b_1,b_2}, \\ E^{b_3,c_4} - E^{c_2,c_4}, \ E^{c_3,c_5} - E^{c_2,c_5}, \ E^{c_3,c_6} - E^{c_6,c_2}, \\ E^{c_1,c_3} + E^{b_3,c_1}, \ E^{b_2,c_3} + E^{b_2,b_3}, \ E^{b_3,b_1} - E^{b_1,c_2}, \\ &- E^{b_1,c_5} - E^{c_3,c_5}, \ E^{c_4,c_6} - E^{c_3,c_6}, \ E^{c_1,c_4} - E^{c_1,c_3}, \\ E^{c_2,c_4} - E^{b_1,c_2}, \ - E^{b_1,b_2} - E^{b_2,c_3}, \ E^{b_3,c_4} - E^{b_3,b_1}, \\ E^{b_2,c_6} - E^{c_4,c_6}, \ E^{c_5,c_1} - E^{c_1,c_4}, \ E^{c_2,c_5} - E^{c_2,c_4}, \\ E^{c_3,c_5} + E^{b_2,c_3}, \ E^{b_1,c_5} + E^{b_1,b_2}, \ E^{b_2,b_3} - E^{b_3,c_4}, \\ &- E^{b_3,c_1} - E^{c_5,c_1}, \ E^{c_6,c_2} - E^{c_2,c_5}, \ E^{c_3,c_6} - E^{c_3,c_5}, \\ E^{c_4,c_6} - E^{d_3,c_4}, \ - E^{b_3,b_1} - E^{b_1,c_5}, \ E^{b_2,c_6} - E^{b_2,b_3}. \end{split}$$

Then we have

$$[E^{c_1,c_3}] = [E^{c_2,c_4}] = [E^{c_3,c_5}] = [E^{c_4,c_6}] = [E^{c_5,c_1}] = [E^{c_6,c_2}]$$

= $[E^{c_1,c_4}] = [E^{c_2,c_5}] = [E^{c_3,c_6}] = [E^{b_1,b_2}] = [E^{b_2,b_3}] = [E^{b_3,b_1}]$
= $[E^{b_1,c_2}] = [E^{b_3,c_4}] = [E^{b_2,c_6}]$
= $-[E^{b_1,c_5}] = -[E^{b_3,c_1}] = -[E^{b_2,c_3}],$

Then the linking module $L(K_{3,3}) = \langle [E^{c_1,c_3}] \rangle \cong \mathbb{Z}$ and the Wu invariant is given by:

$$\mathcal{L}(f) = \sum_{a \cap b = \emptyset} \varepsilon(a, b) \ell(f(a), f(b))[E^{c_1, c_3}],$$

where $\varepsilon(a, b)$ is defined by $\varepsilon(c_i, c_j) = 1$, $\varepsilon(b_i, b_j) = 1$ and

$$\varepsilon(c_i, b_j) = \begin{cases} 1 & \text{if } c_i \text{ and } b_j \text{ are parallel in Figure 2} \\ -1 & \text{if } c_i \text{ and } b_j \text{ are anti-parallel in Figure 2.} \end{cases}$$

Remark 2.4. It was shown in [17] that L(G) = 0 if and only if G is a planar graph which does not contain a pair of disjoint cycles.

Fig. 3. A reduced Wu invariant for K_6 is given in Example 2.9.

Remark 2.5. It was shown in [7] that if the graph G is 3-connected, then

rank
$$L(G) = \frac{1}{2} \left\{ \beta_1(G)^2 + \beta_1(G) + 4|E(G)| - \sum_{v \in V(G)} (\deg(v))^2 \right\},\$$

where $\beta_1(G)$ denotes the first Betti number of *G* and deg(*v*) denotes the valency of a vertex *v*. For example, rank($L(K_6)$) = 10 and rank($L(K_7)$) = 36.

Definition 2.6. Let f be a spatial embedding of an oriented graph G with linking module L(G) and Wu invariant $\mathcal{L}(f) \in L(G)$. Let $\varepsilon : L(G) \to \mathbb{Z}$ be a homomorphism. Then we call the integer $\varepsilon(\mathcal{L}(f))$ the reduced Wu invariant of f with respect to ε and denote it by $\tilde{\mathcal{L}}_{\varepsilon}(f)$.

For a pair of disjoint edges e_i and e_j , we denote $\varepsilon([E^{e_i,e_j}])$ by $\varepsilon(e_i,e_j)$. Thus

$$\tilde{\mathcal{L}}_{\varepsilon}(f) = \varepsilon \left(\left[\sum_{e_i \cap e_j = \emptyset} \ell(f(e_i), f(e_j)) E^{e_i, e_j} \right] \right) = \sum_{e_i \cap e_j = \emptyset} \ell(f(e_i), f(e_j)) \varepsilon(e_i, e_j).$$

Example 2.7. Consider $2K_3$, labelled and oriented as in Figure 2, and let f be an embedding of $2K_3$ in S^3 . Let ε be the isomorphism from $L(2K_3)$ to \mathbb{Z} defined by $\varepsilon(e_1, d_1) = 1$. Then by Example 2.1, we have $\tilde{\mathcal{L}}_{\varepsilon}(f) = 2\text{lk}(f)$.

Example 2.8. Let *G* be K_5 or $K_{3,3}$ labelled and oriented as illustrated in Figure 2, and let *f* be an embedding of *G* in S^3 . Let ε be the isomorphism from L(G) to \mathbb{Z} defined by $\varepsilon(e_1, e_3) = 1$ for $G = K_5$ and $\varepsilon(c_1, c_3) = 1$ for $G = K_{3,3}$. Then it follows that $\tilde{\mathcal{L}}_{\varepsilon}(f) = \sum_{a \cap b = \emptyset} \varepsilon(a, b) \ell(f(a), f(b))$, where the value of $\varepsilon(a, b)$ for an arbitrary pair of edges is given in Example 2.2 if $G = K_5$ and in Example 2.3 if $G = K_{3,3}$.

Example 2.9. Consider K_6 , labelled and oriented as in Figure 3, and let f be an embedding of K_6 in S^3 . For any pair of disjoint edges a and b in K_6 , we define $\varepsilon(a, b)$ as follows:

 $\varepsilon(x_i, x_j) = \begin{cases} 3 & \text{if } x_i \text{ and } x_j \text{ are anti-parallel in Figure 3} \\ 2 & \text{if } x_i \text{ and } x_j \text{ are neither parallel nor anti-parallel in Figure 3}; \end{cases}$ $\varepsilon(y_i, y_j) = \begin{cases} 0 & \text{if } y_i \text{ and } y_j \text{ are anti-parallel in Figure 3} \\ -1 & \text{if } y_i \text{ and } y_j \text{ are neither parallel nor anti-parallel in Figure 3}; \end{cases}$ $\varepsilon(x_i, z_j) = \begin{cases} -1 & \text{if } x_i \text{ and } z_j \text{ are anti-parallel in Figure 3} \\ 1 & \text{if } x_i \text{ and } z_j \text{ are parallel in Figure 3}. \end{cases}$

In addition, we define $\varepsilon(z_i, z_j) = 1$, $\varepsilon(x_i, y_j) = -1$, and $\varepsilon(y_i, z_j) = 0$. Then it can

Fig. 4. The Reidemeister moves for embedded graphs.

be checked that ε gives a homomorphism from $L(K_6)$ to \mathbb{Z} . It follows that $\tilde{\mathcal{L}}_{\varepsilon}(f) = \sum_{a \cap b = \emptyset} \varepsilon(a, b) \ell(f(a), f(b))$ is a reduced Wu invariant for K_6 .

3. Generalized Simon invariants

Simon introduced the following function of embeddings f of the graphs K_5 and $K_{3,3}$, labeled and oriented as in Figure 2. Let

$$\widehat{L}_{\varepsilon}(f) = \sum_{a \cap b = \emptyset} \varepsilon(a, b) \ell(f(a), f(b))$$

where $\varepsilon(a, b)$ is defined as $\varepsilon(e_i, e_j) = 1$, and $\varepsilon(d_i, d_j) = \varepsilon(e_i, d_j) = -1$ for K_5 ; and $\varepsilon(a, b)$ is defined as $\varepsilon(c_i, c_j) = 1$, $\varepsilon(b_i, b_j) = 1$,

$$\varepsilon(c_i, b_j) = \begin{cases} 1 & \text{if } c_i \text{ and } b_j \text{ are parallel in Figure 2} \\ -1 & \text{if } c_i \text{ and } b_j \text{ are anti-parallel in Figure 2,} \end{cases}$$

for $K_{3,3}$.

Simon then proved that for any projection of an embedding f of the oriented labelled graphs K_5 and $K_{3,3}$, the value of

$$\sum_{a,b\in G} \varepsilon(a,b)\ell(f(a),f(b))$$

is invariant under the five Reidemeister moves for spatial graphs given in Figure 4. This invariant is known as the *Simon invariant*.

By using Simon's method we can create similar invariants for many other embedded graphs. In particular, let G be an oriented graph and let f be an embedding of G in S^3 . If we can define a function $\varepsilon(a, b)$ from the set of pairs of disjoint edges of G to the integers such that for any projection of f(G) the value of

$$\widehat{L}_{\varepsilon}(f) = \sum_{a \cap b = \emptyset} \varepsilon(a, b) \ell(f(a), f(b))$$

is invariant under the five Reidemeister moves, then we say that $\widehat{L}_{\varepsilon}(f)$ is a generalized Simon invariant of f(G). If for every embedding f of G, $\widehat{L}_{\varepsilon}(f)$ is a generalized Simon invariant of f(G), then we say that $\widehat{L}_{\varepsilon}(f)$ is a generalized Simon invariant of G.

Observe that the reduced Wu invariants given in Example 2.8 are identical to their Simon invariants. In fact, every reduced Wu invariant with respect to a given homomorphism ε is a

526

Fig. 5. An illustration of the oriented K_7 , with the 0-star in black, the 1-star in bold, and the 2-star in grey. generalized Simon invariant with epsilon coefficients given by $\varepsilon(a, b)$. However, not every generalized Simon invariant is necessarily a reduced Wu invariant. In order to distinguish these two types of invariants, we use $\tilde{\mathcal{L}}_{\varepsilon}(f)$ to denote a reduced Wu invariant and $\hat{\mathcal{L}}_{\varepsilon}(f)$ to denote a generalized Simon invariant.

We say that a graph embedded in S^3 is *achiral* if there is an orientation reversing homeomorphism of S^3 that takes the graph to itself setwise. Otherwise, we say the embedded graph is *chiral*. We say that an abstract graph is *intrinsically chiral* if every embedding of the graph in S^3 is chiral. Note that when we talk about chirality or achirality we are considering embedded graphs as subsets of S^3 disregarding any edge labels or orientations. For example, we saw in Figure 1 that K_5 and $K_{3,3}$ have achiral embeddings, although it was shown in [8] that no embedding of either of these graphs has an orientation reversing homeomorphism that preserves the edge labels and orientations given in Figure 2.

We now define generalized Simon invariants for some specific graphs and families of graphs, and use these invariants to prove that the graphs are intrinsically chiral.

The complete graph K_7

Consider the complete graph K_7 with labelled edges as illustrated in Figure 5. We refer to the edges $x_1, x_2, ..., x_7$ as "outer edges" and the rest of the edges as "inner edges." We refer to the Hamiltonian cycle $\overline{y_1y_2...y_7}$ as the 1-*star* since these edges skip over one vertex relative to the cycle $\overline{x_1x_2...x_7}$. Similarly, we refer to the Hamiltonian cycle $\overline{z_1z_2...z_7}$ as the 2*star* since these edges skip over two vertices relative to the cycle $\overline{x_1x_2...x_7}$. For consistency, we also use the term 0-*star* to refer to the Hamiltonian cycle $\overline{x_1x_2...x_7}$. We orient the edges around each of the stars as illustrated. Note that this classification of oriented edges is only dependent on our initial choice of an oriented 0-star.

We define the epsilon coefficient of a pair of disjoint edges by the function:

$$\varepsilon(x_i, x_j) = \varepsilon(y_i, y_j) = \varepsilon(z_i, z_j) = \varepsilon(x_i, z_j) = \varepsilon(y_i, z_j) = 1$$
$$\varepsilon(x_i, y_j) = -1.$$

Given an oriented 0-star and an embedding $f : K_7 \to S^3$ with a regular projection, we define the integer $\widehat{L}_{\varepsilon}(f)$ by

$$\widehat{L}_{\varepsilon}(f) = \sum_{a \cap b = \varnothing} \varepsilon(a, b) \ell(f(a), f(b)).$$

LEMMA 3.1. Consider K_7 with a fixed choice of an oriented 0-star. Then for any embedding $f : K_7 \to S^3$, the value of $\widehat{L}_{\varepsilon}(f)$ is an ambient isotopy invariant.

Proof. It is easy to check that $\widehat{L}_{\varepsilon}(f)$ is invariant under the first four Reidemeister moves. In order to show that $\widehat{L}_{\varepsilon}(f)$ is invariant under the fifth move, we must show that the value

Fig. 6. K_7 with an edge pulled over a vertex.

is unchanged when any edge of $f(K_7)$ is pulled over or under a given vertex v. An example is illustrated in Figure 6.

Pulling a given edge e over a vertex will generate six new crossings. In Figure 6 the edge x_4 has new crossings with the edges x_1 , y_1 , z_1 , x_2 , y_3 , and z_4 . The crossings with edges pointed away from the vertex (x_1, y_1, z_1) will have an opposite sign compared to the crossings with edges pointed toward the vertex (x_2, y_3, z_4) . Thus, the overall change in $\hat{L}_{\varepsilon}(f)$ is found by adding the epsilon coefficients for the crossings of x_4 with x_1 , y_1 , and z_1 and subtracting the epsilon coefficients for the crossings of x_4 with x_2 , y_3 , and z_4 . It is easy to check that $\hat{L}_{\varepsilon}(f)$ is unchanged in each case.

It follows from Lemma 3.1, that $\widehat{L}_{\varepsilon}(f)$ is a generalized Simon invariant.

Remark 3.2. One can check that the epsilon coefficients we have given for K_7 define a homomorphism from the free \mathbb{Z} -module $L(K_7)$ to \mathbb{Z} . Thus $\widehat{L}_{\varepsilon}(f)$ also gives us a reduced Wu invariant for K_7 .

We now apply the generalized Simon invariant of K_7 to prove that K_7 is intrinsically chiral. This result was previously proven by Flapan and Weaver [3], but using the generalized Simon invariant allows us to give a simpler proof which can be generalized to apply to many other graphs. We begin with a lemma.

LEMMA 3.3. For any embedding f of K_7 in S^3 , the generalized Simon invariant $\widehat{L}_{\varepsilon}(f)$ is an odd number.

Proof. Since any crossing change will change the signed crossing number between two edges by ± 2 , we only need to find an embedding f where $\hat{L}_{\varepsilon}(f)$ is odd. Consider an embedding of K_7 which has Figure 5 as its projection with the intersections between edges replaced by crossings. Note that there are 35 crossings in this embedding of K_7 : 14 crossings of the 2-star with itself, and 21 crossings between the 1-star and the 2-star. The epsilon coefficient for every one of these crossings is 1. Since there is an odd number of crossings, regardless of their signs, $\hat{L}_{\varepsilon}(f)$ must be odd. Because any crossing change will change $\hat{L}_{\varepsilon}(f)$ by an even number, it follows that $\hat{L}_{\varepsilon}(f)$ is odd for any embedding of K_7 .

THEOREM 3.4. K_7 is intrinsically chiral.

Proof. For the sake of contradiction, suppose that for some embedding f of K_7 there is an orientation reversing homeomorphism h of the pair $(S^3, f(K_7))$. Let α denote the automorphism of K_7 that is induced by h.

Let J denote the set of Hamiltonian cycles in $f(K_7)$ with non-zero Arf invariant. Since any homeomorphism of S^3 preserves the Arf invariant of a knot, the homeomorphism h permutes the elements of J. It follows from Conway and Gordon [1] that |J| must be odd, and hence there is an orbit O in J such that |O| = n for some odd number n. Consequently, h^n setwise fixes an element of O. Hence some Hamiltonian cycle C with non-zero Arf invariant is setwise fixed by h^n . We now label and orient the edges of K_7 as in Figure 5 so that f takes the 0-star of K_7 to C. Since h^n leaves C setwise invariant, the automorphism α^n (induced on K_7 by h^n) leaves the 0-star, 1-star and 2-star all setwise invariant.

Fix a sphere of projection *P* in *S*³. Since $f \circ \alpha^n(K_7)$ and $f(K_7)$ are identical as subsets of *S*³, their projections on *P* are the same. Furthermore, if α^n preserves the orientation of the 0-star, then α^n preserves the orientation of the 1-star and 2-star and hence of every edge. Otherwise, α^n reverses the orientation of every edge. In either case, a given crossing in the projection has the same sign whether it is considered with orientations induced by $\alpha^n(K_7)$ or with orientations induced by K_7 . Furthermore, since α^n leaves the 0-star, 1-star, and 2-star of K_7 setwise invariant, each crossing has the same epsilon coefficient, whether the crossing is considered in $f \circ \alpha^n(K_7)$ or in $f(K_7)$. It follows that $\hat{L}_{\varepsilon}(h^n \circ f) = \hat{L}_{\varepsilon}(\alpha^n \circ f) = \hat{L}_{\varepsilon}(f)$.

Let ρ denote a reflection of S^3 which pointwise fixes the sphere of projection P. Using orientations induced by K_7 , we see that the sign of every crossing in the projection of $\rho \circ f(K_7)$ on P is the reverse of that of the corresponding crossing in the projection of $f(K_7)$. Using the oriented 0-star from K_7 , it follows that $\hat{L}_{\varepsilon}(\rho \circ f) = -\hat{L}_{\varepsilon}(f)$. On the other hand, since n is odd h^n is orientation reversing and is thus isotopic to ρ . Hence by Lemma 3.1, $\hat{L}_{\varepsilon}(\rho \circ f) = \hat{L}_{\varepsilon}(h^n \circ f)$. Consequently, $\hat{L}_{\varepsilon}(h^n \circ f) = -\hat{L}_{\varepsilon}(f)$. Thus $\hat{L}_{\varepsilon}(f) = 0$, which contradicts Lemma 3.3. Hence in fact, K_7 is intrinsically chiral.

COROLLARY 3.5. For every odd number n, the complete graph K_{4n+3} is intrinsically chiral.

Proof. Suppose that for some embedding f of K_{4n+3} in S^3 , there is an orientation reversing homeomorphism h of $(S^3, f(K_{4n+3}))$. Even though in general the homeomorphism h will not have finite order, the automorphism that h induces on K_{4n+3} does have finite order and its order can be expressed as $2^a b$ for some odd number b. Now $g = h^b$ is an orientation reversing homeomorphism of $(S^3, f(K_{4n+3}))$ which induces an automorphism of K_{4n+3} of order 2^a .

Observe that the number of K_7 subgraphs in K_{4n+3} is

$$\frac{(4n+3)(4n+2)(4n+1)(4n)(4n-1)(4n-2)(4n-3)}{7!} = \frac{(4n+3)(2n+1)(4n+1)(n)(4n-1)(2n-1)(4n-3)}{315}$$

This number is odd, since *n* is odd. Thus *g* leaves invariant some K_7 subgraph. But this is impossible since by Theorem 3.4, K_7 is intrinsically chiral.

Mobius ladders

A Möbius ladder M_n with *n* rungs is the graph obtained from a circle with 2n vertices by adding an edge between every pair of antipodal vertices. Let $N \ge 2$, and consider the oriented labeled graph of M_{2N+1} illustrated in Figure 7 (note there is no vertex at the center of the circle). We denote the "outer edges" consecutively as $x_1, x_2, ..., x_{2(2N+1)}$, and the "inner edges" consecutively as $y_1, y_2, ..., y_{2N+1}$. Since $N \ge 2$, it follows from Simon [15] that there is no automorphism of M_{2N+1} which takes an outer edge to an inner edge. Thus, the distinction between inner and outer edges does not depend on any particular labeling.

Fig. 7. An oriented M_{2N+1} .

For any pair of edges *a* and *b*, let the minimal outer edge distance d(a, b) be defined as the minimum number of edges of any path between *a* and *b* using only outer edges (not counting *a* and *b*). For M_{2N+1} , note that $d(x_i, x_j) \leq 2N$ for any *i*, *j*. We define the epsilon coefficient $\varepsilon(a, b)$ of a pair of disjoint edges *a* and *b* by:

$$\varepsilon(x_{i}, x_{j}) = \begin{cases} 2 & \text{if } d(x_{i}, x_{j}) \text{ is odd and } d(x_{i}, x_{j}) \neq 2N - 1 \\ -1 & \text{if } d(x_{i}, x_{j}) = 2N \\ 1 & \text{otherwise,} \end{cases}$$

$$\varepsilon(x_{i}, y_{j}) = \begin{cases} 2 & \text{if } d(x_{i}, y_{j}) = 1 \\ 3 & \text{if } d(x_{i}, y_{j}) \geqslant 2, \end{cases}$$

$$\varepsilon(y_{i}, y_{j}) = \begin{cases} 2 & \text{if } d(y_{i}, y_{j}) = 1 \\ 5 & \text{if } d(y_{i}, y_{j}) = 2 \\ 6 & \text{if } d(y_{i}, y_{j}) \geqslant 3. \end{cases}$$

For any embedding $f: M_{2N+1} \rightarrow S^3$ with a regular projection, define:

$$\widehat{L}_{\varepsilon}(f) = \sum_{a \cap b = \varnothing} \varepsilon(a, b) \ell(f(a), f(b)).$$

Remark 3.6. This definition of $\widehat{L}_{\varepsilon}(f)$ does not reduce to the original Simon invariant for N = 1.

THEOREM 3.7. For $N \ge 2$ and any embedding f of M_{2N+1} in S^3 , $\widehat{L}_{\varepsilon}(f)$ is independent of labeling and orientation, and invariant under ambient isotopy of $f(M_{2N+1})$.

Proof. We first show that $\hat{L}_{\varepsilon}(f)$ is independent of labeling and orientation. Since $N \ge 2$, it follows from Simon [15] that any automorphism of M_{2N+1} with $N \ge 2$ takes the cycle of outer edges $\overline{x_1x_2...x_{4N+2}}$ to itself, preserving the order of the edges $x_1, x_2, ..., x_{4N+2}$ and thus the edges $y_1, y_2, ..., y_{2N+1}$ as well. Thus any automorphism either preserves all the arrows in the orientation of M_{2N+1} , or reverses all the arrows. Reversing every arrow would have no effect on the signs of the crossings, so $\hat{L}_{\varepsilon}(f)$ is independent of labelling and orientation.

As before, it is easy to see that $\widehat{L}_{\varepsilon}(f)$ is invariant under the first four Reidemeister moves. We show that $\widehat{L}_{\varepsilon}(f)$ is unchanged under the fifth Reidemeister move. Without loss of generality, we may assume that an edge e is pulled over a vertex v and the adjacent outer edges point towards v (see Figure 8). Pulling e over v generates three new crossings: two with outer edges and one with an inner edge. We must determine the change in $\widehat{L}_{\varepsilon}(f)$ as a result of of these added crossings.

Fig. 8. M_{2N+1} with an edge *e* pulled over a vertex *v*.

Below we compute the possibilities for the change $\Delta \hat{L}_{\varepsilon}(f)$, and show that in all cases this value is zero. The crossings between the edge e and the two outer edges have the same sign while the crossing of e with an inner edge has the opposite sign. The epsilon coefficients for the crossings of e with the two outer edges are given in parenthesis (with the edge whose minimal outer edge distance from e is larger given first, and the edge closer to egiven second), while the epsilon coefficient of the crossing of e with the inner edge is given afterward. For ease of notation, let d(e, v) denote the minimum number of edges in any path between e and v using only outer edges and not counting e.

(i) e is an outer edge

(a) If
$$d(e, v) = 1$$
, then
 $\Delta \hat{L}_{\varepsilon}(f) = (2+0) - 2 = 0.$

- (b) If d(e, v) = 2, 4, ..., 2N 2, then $\Delta \hat{L}_{\varepsilon}(f) = (1+2) - 3 = 0.$
- (c) If d(e, v) = 3, 5, ..., 2N 3, then $\Delta \hat{L}_{\varepsilon}(f) = (2+1) - 3 = 0.$
- (d) If d(e, v) = 2N 1, then $\Delta \hat{L}_{\varepsilon}(f) = (1+1) - 2 = 0.$
- (e) If d(e, v) = 2N, then $\Delta \widehat{L}_{\varepsilon}(f) = (-1+1) - 0 = 0.$
- (ii) e is an inner edge
 - (a) If d(e, v) = 1, then $\Delta L(f) = (2+0) - 2 = 0$.
 - (b) If d(e, v) = 2, then $\Delta L(f) = (3+2) - 5 = 0$.
 - (c) If $d(e, v) \ge 3$, then $\Delta L(f) = (3+3) - 6 = 0$.

Thus $\widehat{L}_{\varepsilon}(f)$ is invariant under the fifth Reidemeister move, and so it is invariant under ambient isotopy

It follows that $\widehat{L}_{\varepsilon}(f)$ is a generalized Simon invariant for M_{2N+1} .

LEMMA 3.8. For any $N \ge 2$ and any embedding f of M_{2N+1} in S^3 , the generalized Simon invariant $\widehat{L}_{\varepsilon}(f)$ is an odd number.

Proof. Note that any crossing change of a projection of $f(M_{2N+1})$ will change the signed crossing number between the two edges by ± 2 . Thus any crossing change will alter $\widehat{L}_{\varepsilon}(f)$

Fig. 9. An embedding of M_{2N+1} with $\widehat{L}_{\varepsilon}(f) = 1$.

by an even number. Now consider the embedding f of M_{2N+1} shown in Figure 9. There is only one crossing, and it is between two outer edges with an outer edge distance of 2N(the maximum). The epsilon coefficient for this crossing is -1, which is multiplied by the crossing sign -1 so that $\hat{L}_{\varepsilon}(f) = (-1)(-1) = 1$ for this embedding. It follows that $\hat{L}_{\varepsilon}(f)$ is odd for any embedding of M_{2N+1} .

LEMMA 3.9. Let $N \ge 2$. If α is an automorphism of M_{2N+1} , then the epsilon coefficients of M_{2N+1} and $\alpha(M_{2N+1})$ are the same, and α either preserves the orientation of every edge or reverses the orientation of every edge.

Proof. Let $\alpha \in Aut(M_{2N+1})$. Since $N \ge 2$, it follows from Simon [15] that α takes the cycle $\overline{x_1x_2...x_{4N+2}}$ to itself, preserving the order of the edges $x_1, x_2, ..., x_{4N+2}$ and thus preserving the order of the edges $y_1, y_2, ..., y_{2N+1}$ as well. Because the order of the outer edges is preserved, the outer edge distance is also preserved. The epsilon coefficients depend only on the outer edge distance and the distinction between inner and outer edges, so it follows that the epsilon coefficients of M_{2N+1} and $\alpha(M_{2N+1})$ are the same.

Finally, we can see from Figure 7 that α either preserves all or reverses all the orientations on edges.

To prove that M_{2N+1} is intrinsically chiral, we will use the following Proposition whose proof is similar to that of Theorem 3.4.

PROPOSITION 3.10. Let G be an oriented graph with a generalized Simon invariant $\widehat{L}_{\varepsilon}(f)$. Suppose that $\widehat{L}_{\varepsilon}(f)$ is odd for every embedding $f : G \to S^3$, and every automorphism of G preserves the epsilon coefficients of G and either preserves the orientation of every edge or reverses the orientation of every edge. Then G is intrinsically chiral.

Proof. For the sake of contradiction, suppose that for some embedding f of G, there is an orientation reversing homeomorphism h of the pair $(S^3, f(G))$. Let α denote the automorphism that h induces on G.

Fix a sphere of projection *P* in S^3 . Since $f \circ \alpha(G)$ and f(G) are identical as subsets of S^3 , their projections on *P* are the same. Also, since α either preserves all the edge orientations or reverses all the edge orientations, the sign of every crossing in the projection of the oriented embedded graph $h \circ f(G)$ is the same as it is in the projection of the oriented embedded graph f(G). Furthermore, by hypothesis each crossing has the same epsilon coefficient, whether the crossing is considered in $f \circ \alpha(G)$ or in f(G). It follows that $\hat{L}_{\varepsilon}(h^{\circ}f) = \hat{L}_{\varepsilon}(\alpha \circ f) = \hat{L}_{\varepsilon}(f)$.

Let ρ denote a reflection of S^3 which pointwise fixes the sphere of projection P. Using orientations induced by G, the sign of every crossing in the projection of $\rho \circ f(G)$ is the reverse of that of the corresponding crossing in f(G). It follows that $\widehat{L}_{\varepsilon}(\rho \circ f) = -\widehat{L}_{\varepsilon}(f)$.

Fig. 10. An embedding of M_{2N+1} with $\hat{L}_{\varepsilon}(f) = 2k + 1$ with a rotation of the outer loop of order 4N + 2 together with a reflection of the outer loop.

On the other hand, since h is orientation reversing it is isotopic to ρ . Hence by definition of a generalized Simon invariant, $\widehat{L}_{\varepsilon}(\rho \circ f) = \widehat{L}_{\varepsilon}(h \circ f)$. Consequently, $\widehat{L}_{\varepsilon}(h \circ f) = -\widehat{L}_{\varepsilon}(f)$. Thus $\widehat{L}_{\varepsilon}(f) = 0$, which contradicts our hypothesis that $\widehat{L}_{\varepsilon}(f)$ is odd. Hence G is intrinsically chiral.

Flapan [2] showed that M_{2N+1} is intrinsically chiral. However, now that result follows as an immediate corollary of Lemmas 3.8, 3.9 and Proposition 3.10.

COROLLARY 3.11. M_{2N+1} is intrinsically chiral for $N \ge 2$.

Nikkuni and Taniyama [12] showed that the Simon invariant provides restrictions on the symmetries of a given embedding of K_5 or $K_{3,3}$. For example, they proved that for both K_5 and $K_{3,3}$, the transposition of two vertices can be induced by a homeomorphism on an embedding f only if the Simon invariant of the embedding is ± 1 . By contrast we have the following result for M_{2N+1} .

THEOREM 3.12. Let $N \ge 2$. Then for any odd integer m, there is an embedding f of M_{2N+1} in S^3 with $\widehat{L}_{\varepsilon}(f) = m$ such that every automorphism of M_{2N+1} is induced by a homeomorphism of $(S^3, f(M_{2N+1}))$.

Proof. Let *m* be an odd integer, and suppose that |m| = 2k+1. Since any automorphism of M_{2N+1} takes the outer loop $x_1x_2...x_{4N+2}$ to itself [15], the automorphism group Aut (M_{2N+1}) is the dihedral group $D_{2(4N+2)}$. This group is generated by a rotation of the outer loop of order 4N + 2 together with a reflection of the outer loop. Hence, it suffices to show there is an embedding $f : M_{2N+1} \to S^3$ with $\hat{L}_{\varepsilon}(f) = m$ such that both of the generators of Aut (M_{2N+1}) are induced by homeomorphisms of $(S^3, f(M_{2N+1}))$.

Consider the embedding of $f: M_{2N+1} \to S^3$ shown in Figure 10. There are 2k + 1 crossings between a pair of outer edges with an outer edge distance of 2N. The epsilon coefficient for each of these crossings is -1. If m > 0, we embed M_{2N+1} so that all the crossings have negative sign, otherwise embed M_{2N+1} so that the crossings all have positive sign. Then $\hat{L}_{\varepsilon}(f) = (-1)(-1)(2k+1) = 2k+1$ if m > 0, and $\hat{L}_{\varepsilon}(f) = (-1)(+1)(2k+1) = -(2k+1)$ if m < 0. Since |m| = 2k + 1, it follows that $\hat{L}_{\varepsilon}(f) = m$.

By inspection of Figure 10 we see that both generators of $Aut(M_{2N+1})$ can be induced by homeomorphisms of $(S^3, f(M_{2N+1}))$.

Observe that $M_3 = K_{3,3}$. Using our generalized Simon invariant for embeddings of M_{2N+1} (*with* $N \ge 2$) and the original Simon invariant for embeddings of $M_3 = K_{3,3}$, we now define a topological invariant for embedded Mobius ladders with an even number of rungs (at least 4). For the remainder of this section, we use $\hat{L}_{\varepsilon}(f)$ to refer to the Simon invariant if f is an

embedding of M_3 and to the generalized Simon invariant if f is an embedding of M_{2N+1} for $N \ge 2$.

Let $N \ge 2$ and let f be an embedding of M_{2N} in S^3 . For each $i \le 2N$, let $g_i : M_{2N} \to S^3$ be the embedding obtained from f by omitting the rung r_i and its vertices from M_{2N} . Note that since N > 1 the rungs of M_{2N} are setwise invariant under any automorphism [15]. Thus the definition of g_i is unambiguous. When N > 2, by Theorem 3.7, the graph M_{2N-1} has a well defined $\hat{L}_{\varepsilon}(g_i)$ independent of labelling and orientation. When N = 2, we label each M_3 subgraph such that the rungs and outer edges of M_3 are contained in the rungs and outer edges of M_4 respectively. Although there are two possible orientations for each embedded M_3 subgraph, one can be obtained from the other by reversing the orientation of all edges. This has no effect on the crossing signs (or epsilon coefficients). Thus we can unambiguously define:

$$T_{\varepsilon}(f) = \sum_{i \leq 2N} \widehat{L}_{\varepsilon}(g_i).$$

Note that $T_{\varepsilon}(f)$ is defined on an embedding of the unoriented graph M_{2N} .

THEOREM 3.13. For $N \ge 2$ and any embedding f of M_{2N} in S^3 , $T_{\varepsilon}(f)$ is invariant under ambient isotopy. Furthermore, if $T_{\varepsilon}(f) \neq 0$, then f is a chiral embedding of M_{2N} .

Proof. By [15], the cycle of outer edges of M_{2N} is unique. Each $\hat{L}_{\varepsilon}(g_i)$ is invariant under ambient isotopy by Theorem 3.7 when N > 2 and by the Simon invariant when N = 2. Thus it follows that $T_{\varepsilon}(f)$ is also invariant under ambient isotopy.

Let *h* denote an orientation reversing homeomorphism of S^3 . Then *h* will reverse the signs of all the crossings of $f(M_{2N})$ (and thus each $g_i(M_{2N-1})$). We now show that the automorphism that *h* induces on each M_{2N-1} preserves the epsilon coefficients. If $N \ge 3$, then this follows directly from Lemma 3.9. If instead N = 2, then by Simon [15] the outer edges of M_{2N} are setwise invariant under the automorphism that *h* induces on M_{2N} , so *h* preserves the distinction between inner and outer edges. As explained earlier, the edges in each $g_i(M_3)$ subgraph of $f(M_4)$ are labelled as inner or outer in order to match $f(M_4)$. It follows that *h* also preserves the distinction between inner and outer edges for each M_3 subgraph. For M_3 , the epsilon coefficients depend only on the distinction between inner and outer edges and on the relative orientation of edges (which is invariant under any automorphism), so the automorphism that *h* induces on each M_3 subgraph preserves the epsilon coefficients.

Since the epsilon coefficients are preserved and the crossing signs are reversed, it follows that each $\widehat{L}_{\varepsilon}(h \circ g_i) = -\widehat{L}_{\varepsilon}(g_i)$ and so $T_{\varepsilon}(h(f)) = -T(f)$. If $T_{\varepsilon}(f) \neq 0$, then $T_{\varepsilon}(f) \neq -T_{\varepsilon}(f) = T_{\varepsilon}(h(f))$, and thus $f(M_{2N})$ is chiral.

COROLLARY 3.14. For all $N \ge 2$, $m \ge 0$, the embedding f of M_{2N} shown in Figure 11 is chiral.

Proof. For all of the $f(M_{2N-1})$ subgraphs, the outer edge distance between the two crossed edges is 2N - 2, so the crossing sign and epsilon coefficient for each of the 2m + 1 crossings is the same. This epsilon coefficient is 1 for M_3 when N = 2, and -1 for the generalized Simon invariant (if N > 2). Since all of the 2N subgraphs have the same epsilon coefficient and sign for each crossing, both of which are ± 1 , it follows that $T_{\varepsilon}(f) = (\pm 1)(\pm 1)(2N)(2m + 1)$ for the embedding f in Figure 11. Since $N \ge 2$ and $m \ge 0$, this means $T_{\varepsilon}(f) \pm 0$ and thus the embedding is chiral by Theorem 3.13.

Fig. 11. An embedding of M_{2N} with 2m + 1 crossings.

Fig. 12. An oriented Heawood graph.

The Heawood graph

Let C_{14} denote the Heawood graph oriented and labelled as in Figure 12. In particular, we refer to its "outer edges" consecutively by $x_1, x_2, ..., x_{14}$, and its "inner edges" consecutively by $y_1, y_2, ..., y_7$. We note that this classification of oriented edges is only dependent on the labeling of the edges in the Hamiltonian cycle $\overline{x_1 x_2 ... x_{14}}$.

For any pair of edges *a* and *b*, let the minimal outer edge distance d(a, b) be defined as the minimum number of edges in any path between *a* and *b* using only outer edges (not counting *a* and *b*). For any *i*, *j*, note that $d(x_i, x_j) \leq 6$, $d(x_i, y_j) \leq 4$, and $d(y_i, y_j) \leq 2$.

We define the epsilon coefficient $\varepsilon(a, b)$ of a pair of disjoint edges by:

$$\varepsilon(x_i, x_j) = \begin{cases} 2 & \text{if } d(x_i, x_j) = 1 \text{ or } 4 \\ -2 & \text{if } d(x_i, x_j) = 3 \text{ or } 5, \text{ and } x_i, x_j \text{ are connected by an edge} \\ -3 & \text{if } d(x_i, x_j) = 5, \text{ and } x_i, x_j \text{ are not connected by an edge} \\ 5 & \text{if } d(x_i, x_j) = 6 \\ 1 & \text{otherwise}, \end{cases}$$
$$\varepsilon(x_i, y_j) = \begin{cases} 2 & \text{if } d(x_i, y_j) = 1 \\ 3 & \text{if } d(x_i, y_j) = 2 \text{ or } 4 \\ -1 & \text{if } d(x_i, y_j) = 3, \end{cases}$$
$$\varepsilon(y_i, y_j) = \begin{cases} 2 & \text{if } d(y_i, y_j) = 1 \\ 5 & \text{if } d(y_i, y_j) = 2. \end{cases}$$

For any embedding $f: C_{14} \rightarrow S^3$ with a regular projection, define

$$\widehat{L}_{\varepsilon}(f) = \sum_{a \cap b = \emptyset} \varepsilon(a, b) \ell(f(a), f(b)).$$

THEOREM 3.15. For any embedding f of C_{14} in S^3 , $\widehat{L}_{\varepsilon}(f)$ is invariant under any ambient isotopy leaving the cycle $\overline{x_1x_2...x_{14}}$ setwise invariant.

Proof. As demonstrated in the previous proofs, we need only to verify that $\hat{L}_{\varepsilon}(f)$ is invariant under the fifth Reidemeister move. It suffices to show that $\hat{L}_{\varepsilon}(f)$ is unchanged when any of the 21 edges in the Heawood graph is pulled over a particular vertex. This is easy to check using the method shown in the proof of Theorem 3.7.

It follows that $\widehat{L}_{\varepsilon}(f)$ is a generalized Simon invariant of C_{14} .

LEMMA 3.16. For any embedding f of C_{14} in S^3 , the generalized Simon invariant $\widehat{L}_{\varepsilon}(f)$ is an odd number.

Proof. Since any crossing change will change the signed crossing number between the two edges by ± 2 , we only need to find an embedding f where $\hat{L}_{\varepsilon}(f)$ is odd. Consider an embedding of the Heawood graph which has Figure 12 as its projection with the intersections between edges replaced by crossings. The reader can check that regardless of the signs of the crossings, there are an odd number of crossings with odd epsilon coefficient. Hence $\hat{L}_{\varepsilon}(f)$ is an odd number.

The proof of the following lemma is left as an exercise.

LEMMA 3.17. Let α be an automorphism of C_{14} that takes the Hamiltonian cycle $\overline{x_1x_2...x_{14}}$ to itself. Then corresponding epsilon coefficients of C_{14} and $\alpha(C_{14})$ are equal, and α either preserves the orientation of every edge or reverses the orientation of every edge.

THEOREM 3.18. The Heawood graph is intrinsically chiral.

Proof. Let C_{14} denote the Heawood graph. Suppose that for some embedding f of C_{14} in S^3 , there is an orientation reversing homeomorphism h of $(S^3, f(C_{14}))$. It was shown by Nikkuni [11] that the mod 2 sum of the Arf invariants of all the 14-cycles and 12-cycles in an embedding of C_{14} is 1. Thus $f(C_{14})$ either has an odd number of 14-cycles with Arf invariant 1 or an odd number of 12-cycles with Arf invariant 1. By arguing as in the proof of Corollary 3.5, without loss of generality we can assume that the order of the automorphism that h induces on C_{14} is a power of 2. It follows that h either leaves some 14-cycle or some 12-cycle setwise invariant.

Suppose that *h* leaves a 14-cycle setwise invariant. Label the edges of this 14-cycle consecutively as $\overline{x_1x_2...x_{14}}$. Then it follows from Lemma 3.17, that $\widehat{L}_{\varepsilon}(h \circ f) = \widehat{L}_{\varepsilon}(f)$. But since *h* is orientation reversing we can argue as in the proof of Proposition 3.10 that $\widehat{L}_{\varepsilon}(h \circ f) = -\widehat{L}_{\varepsilon}(f)$, which is impossible since L(f) is odd and hence non-zero.

Now suppose that *h* leaves a 12-cycle *Z* setwise invariant. As shown in Figure 13, *G* has precisely three edges not in *Z* which have both vertices in *Z*. Now *Z* together with these three edges is a Möbius ladder M_3 . However, it was shown in [2] that no embedding of M_3 in S^3 has an orientation reversing homeomorphism which takes the outer loop *Z* to itself. Thus again we have a contradiction.

4. The subgraphs $2K_3$, K_5 and $K_{3,3}$ of a given graph

Shinjo and Taniyama [14] proved that two embeddings f and g of a graph G in S^3 are spatial-graph homologous if and only if for each $2K_3$ subgraph H of G the restriction maps

Fig. 13. A 12-cycle in the Heawood graph.

 $f|_H$ and $g|_H$ have the same linking number, and for each K_5 or $K_{3,3}$ subgraph H of G the restriction maps $f|_H$ and $g|_H$ have the same Simon invariant.

We now show that for any oriented graph G, any integer linear combination of the reduced Wu invariants of subgraphs of G is itself a reduced Wu invariant for G.

THEOREM 4.1. Let G be a graph with oriented edges, and let G_1, G_2, \ldots, G_k denote subgraphs of G with orientations inherited from G. For each $q \leq k$, let $\varepsilon_q : L(G_q) \to \mathbb{Z}$ be a homomorphism, and $i_q : G_q \to G$ be the inclusion map. Let m_1, m_2, \ldots, m_k be integers and let $\varepsilon : L(G) \to \mathbb{Z}$ be the homomorphism given by $\varepsilon = \sum_{q=1}^k m_q \varepsilon_q \circ (i_q \times i_q)^*$. Then for any embedding f of G in S³, $\sum_{q=1}^k m_q \tilde{\mathcal{L}}_{\varepsilon_q}(f|_{G_q})$ is the reduced Wu invariant given by $\tilde{\mathcal{L}}_{\varepsilon}(f)$.

Proof. Observe that the embedding $(f \times f) \circ (i_q \times i_q)$ is equivalent to the embedding $(f|_{G_q}) \times (f|_{G_q}) : C_2(G_q) \to C_2(\mathbb{R}^3)$. Hence, by the definition of the Wu invariant, it follows that

$$\begin{split} \tilde{\mathcal{L}}_{\varepsilon}(f) &= \varepsilon(\mathcal{L}(f)) \\ &= \varepsilon((f \times f)^*(\Sigma)) \\ &= \sum_{q=1}^k m_q \varepsilon_q \circ (i_q \times i_q)^* \circ (f \times f)^*(\Sigma) \\ &= \sum_{q=1}^k m_q \varepsilon_q \circ ((f \times f) \circ (i_q \times i_q))^*(\Sigma) \\ &= \sum_{q=1}^k m_q \varepsilon_q \circ ((f|_{G_q}) \times (f|_{G_q}))^*(\Sigma) \\ &= \sum_{q=1}^k m_q \varepsilon_q (\mathcal{L}(f|_{G_q})) \\ &= \sum_{q=1}^k m_q \tilde{\mathcal{L}}_{\varepsilon_q}(f|_{G_q}). \end{split}$$

Thus we have the result.

This theorem allows us to define new reduced Wu invariants, as we see from the following two examples.

Example 4.2. For $N \ge 2$, consider the oriented labelled graph of a Möbius ladder M_{2N+1} illustrated in Figure 14. For q = 0, 1, ..., 2N, let G_q be the subgraph of M_{2N+1} consisting of the outer cycle $\overline{x_1x_2...x_{4N+2}}$ together with the three rungs y_{q+1} , y_{q+2} , and y_{q+3} where

Fig. 14. An oriented M_{2N+1} together with a $K_{3,3}$ subgraph. Note the subscripts on x_i are considered mod 4N + 2 and those on y_i are considered mod 2N + 1.

the subscripts are considered mod 2N + 1 and the orientations are inherited from M_{2N+1} . Then each G_q is homeomorphic to $K_{3,3}$. Thus each $L(G_q)$ is generated by $[E^{x_{q+1},x_{q+2N+2}}]$. Let ε_q be the homomorphism from $L(G_q)$ to \mathbb{Z} defined by $\varepsilon_q(x_{q+1}, x_{q+2N+2}) = 1$. Let f be an embedding of M_{2N+1} in S^3 . Then by Theorem 4.1, $\tilde{\mathcal{L}}_{\varepsilon}(f) = \sum_{q=0}^{2N} \tilde{\mathcal{L}}_{\varepsilon_q}(f|_{G_q})$ defines a reduced Wu invariant for M_{2N+1} .

Observe that this reduced Wu invariant is not equal to the generalized Simon invariant for M_{2N+1} that we defined in Section 3. However, this invariant has similar properties to those we proved for the generalized Simon invariant of M_{2N+1} . In particular, since each $\tilde{\mathcal{L}}_{\varepsilon_q}(f|_{G_q})$ is essentially the Simon invariant of $f|_{G_q}$ and therefore odd valued, it follows that $\tilde{\mathcal{L}}(f)$ is always odd. Moreover, we know from [15] that any automorphism of M_{2N+1} takes the outer cycle $\overline{x_1x_2...x_{4N+2}}$ to itself. Thus any automorphism of M_{2N+1} leaves $\{G_0, G_1, \ldots, G_{2N}\}$ setwise invariant. This implies that $\tilde{\mathcal{L}}(f)$ is independent of labelling.

Example 4.3. Let C_{14} be the Heawood graph as illustrated in Figure 15. For q = 0, 1, ..., 6, let G_q be the subgraph of C_{14} as illustrated in Figure 15, where the labels of vertices are considered mod 14. Note that each G_q is homeomorphic to $K_{3,3}$. Thus each $L(G_q)$ is generated by $[E^{x_1,x_8}]$. Let ε_q be the homomorphism from $L(G_q)$ to \mathbb{Z} defined by $\varepsilon_q(x_1, x_8) = 1$. Let f be an embedding of C_{14} in S^3 . Then by Theorem 4.1, $\tilde{\mathcal{L}}_{\varepsilon}(f) = \sum_{q=0}^{6} \tilde{\mathcal{L}}_{\varepsilon_q}(f|_{G_q})$ defines a reduced Wu invariant for C_{14} .

Again this reduced Wu invariant is not equal to the generalized Simon invariant for C_{14} that we defined in Section 3, but has similar properties to those of the generalized Simon invariant. In particular, since each $\tilde{\mathcal{L}}_{\varepsilon_q}(f|_{G_q})$ is essentially the Simon invariant of $f|_{G_q}$ and therefore odd valued, it follows that $\tilde{\mathcal{L}}(f)$ is always odd. Moreover, let α be an automorphism of C_{14} takes the outer cycle $\overline{x_1 \dots x_{14}}$ to itself, and thus the edges y_1, y_2, \dots, y_7 as well. Then α permutes $\{G_0, G_1, \dots, G_6\}$ and reversing every arrow would have no effect on the signs of the crossings. This implies that $\tilde{\mathcal{L}}(f)$ is preserved under α .

Now we prove the converse of Theorem 4.1. In particular, we show that any reduced Wu invariant of a graph G can be expressed as a linear combination of reduced Wu invariants of subgraphs $2K_3$, K_5 and $K_{3,3}$ of G.

THEOREM 4.4. Let G be a graph with oriented edges, and let G_1, G_2, \ldots, G_k denote all of the $2K_3, K_5$, and $K_{3,3}$ subgraphs of G with orientations inherited from G. For each $q \leq k$, let $\varepsilon_q : L(G_q) \to \mathbb{Z}$ be an isomorphism, and let $i_q : G_q \to G$ be the inclusion map. Then

Fig. 15. An oriented Heawood graph together with a $K_{3,3}$ subgraph.

for any homomorphism $\varepsilon : L(G) \to \mathbb{Z}$, there exists integers $m \neq 0$ and m_1, m_2, \ldots, m_k such that for any embedding f of G in S^3 .

$$m\tilde{\mathcal{L}}_{\varepsilon}(f) = \sum_{q=1}^{k} m_q \tilde{\mathcal{L}}_{\varepsilon_q}(f|_{G_q})$$

Proof. Consider the homomorphism

$$\varphi: L(G) \longrightarrow \bigoplus_{q=1}^k L(G_q)$$

defined by

$$\varphi(x) = ((i_1 \times i_1)^*(x), (i_2 \times i_2)^*(x), \dots, (i_k \times i_k)^*(x)).$$

Shinjo and Taniyama [14] proved that for any $x, y \in L(G)$, if $(i_q \times i_q)^*(x) = (i_q \times i_q)^*(y)$ for any q = 1, 2, ..., k then x = y. This implies that φ is injective. It follows that φ also induces an injective linear map

$$\varphi: L(G) \otimes \mathbb{Q} \longrightarrow \bigoplus_{q=1}^{k} (L(G_q) \otimes \mathbb{Q})$$

and therefore its dual

$$\varphi^{\sharp}: \operatorname{Hom}\left(\bigoplus_{q=1}^{k} (L(G_q) \otimes \mathbb{Q}), \mathbb{Q}\right) \longrightarrow \operatorname{Hom}(L(G) \otimes \mathbb{Q}, \mathbb{Q})$$

is surjective. We consider each ε_q as a linear map from $\bigoplus_{q=1}^k (L(G_q) \otimes \mathbb{Q})$ to \mathbb{Q} in the usual way. Then because each ε_q is an isomorphism, the linear forms $\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_k$ generate $\operatorname{Hom}(\bigoplus_{q=1}^k (L(G_q) \otimes \mathbb{Q}), \mathbb{Q})$. Thus, for any $u \in \operatorname{Hom}(L(G) \otimes \mathbb{Q}, \mathbb{Q})$, there is a $u' \in \operatorname{Hom}(\bigoplus_{q=1}^k (L(G_q) \otimes \mathbb{Q}), \mathbb{Q})$ and rational numbers r_1, r_2, \ldots, r_k such that $u' = \sum_{q=1}^k r_q \varepsilon_q$.

Hence for an element *x* in $L(G) \otimes \mathbb{Q}$, we have

$$u(x) = \varphi^{\sharp}(u')(x)$$

= $\varphi^{\sharp}\left(\sum_{q=1}^{k} r_q \varepsilon_q\right)(x)$
= $\sum_{q=1}^{k} r_q \varphi^{\sharp}(\varepsilon_q)(x)$
= $\sum_{q=1}^{k} r_q \varepsilon_q(\varphi(x))$
= $\sum_{q=1}^{k} r_q \varepsilon_q \circ (i_q \times i_q)^*(x)$

Now it follows that $\varepsilon_1 \circ (i_1 \times i_1)^*$, $\varepsilon_2 \circ (i_2 \times i_2)^*$, ..., $\varepsilon_k \circ (i_k \times i_k)^*$ generate Hom $(L(G) \otimes \mathbb{Q}, \mathbb{Q})$. Hence, there are rational numbers r_1, r_2, \ldots, r_k such that

$$\tilde{\mathcal{L}}_{\varepsilon}(f) = \sum_{q=1}^{k} r_q \tilde{\mathcal{L}}_{\varepsilon_q}(f|_{G_q}).$$

This implies the desired conclusion.

Example 4.5. Consider the oriented and labelled K_6 illustrated in Figure 16. Let ε be the homomorphism from $L(K_6)$ to \mathbb{Z} given in Example 2.9, and let $\tilde{\mathcal{L}}_{\varepsilon}(f)$ be the corresponding reduced Wu invariant. For q = 1, ..., 6, let G_q be the K_5 subgraphs illustrated in Figure 16 where q is considered mod 6. Observe that the orientations and labels on G_q are inherited from those on K_6 . Then for each q, the linking module $L(G_q)$ is generated by $[E^{x_1,x_4}]$. Let ε_q be the isomorphism from $L(G_q)$ to \mathbb{Z} defined by $\varepsilon_q(x_1, x_4) = 1$. Let f be an embedding of K_6 in S^3 . Then it's not hard to check that:

$$2\tilde{\mathcal{L}}_{\varepsilon}(f) = \sum_{q=1}^{6} \tilde{\mathcal{L}}_{\varepsilon_q}(f|_{G_q}).$$

Example 4.6. Consider the oriented and labelled K_7 illustrated in Figure 5. The epsilon coefficients which gave us the generalized Simon invariant for K_7 are

$$\varepsilon(x_i, x_j) = \varepsilon(y_i, y_j) = \varepsilon(z_i, z_j) = \varepsilon(x_i, z_j) = \varepsilon(y_i, z_j) = 1.$$

$$\varepsilon(x_i, y_j) = -1$$

Fig. 17. We consider these oriented subgraphs of K_7 .

These values of $\varepsilon(a, b)$ define a homomorphism $\varepsilon : L(K_7) \to \mathbb{Z}$, which corresponds to a reduced Wu invariant $\tilde{\mathcal{L}}_{\varepsilon}(f)$. For q = 1, 2, ..., 7, let G_q, H_q, F_q and L_q be the subgraphs of K_7 illustrated in Figure 17, where the subscripts are considered mod 7. Observe that the orientations on the subgraphs are inherited from those of K_7 in Figure 5.

Each G_q , H_q , and F_q is homeomorphic to $K_{3,3}$. Each $L(G_q)$ is generated by $[E^{x_1,x_4}]$, each $L(H_q)$ is generated by $[E^{y_1,y_7}]$ and each $L(F_q)$ is generated by $[E^{z_1,z_3}]$. On the other hand, each J_q is homeomorphic to $2K_3$, and each $L(J_q)$ is generated by $[E^{x_{q+1},x_{q+4}}]$. Let ε_q be the homomorphism from $L(G_q)$ to \mathbb{Z} defined by $\varepsilon_q(x_1, x_4) = 1$. Let ζ_q be the homomorphism from $L(F_q)$ to \mathbb{Z} defined by $\zeta_q(y_1, y_7) = 1$. Let η_q be the homomorphism from $L(F_q)$ to \mathbb{Z} defined by $\eta_q(z_1, z_3) = 1$. Let θ_q be the homomorphism from $L(J_q)$ to \mathbb{Z} defined by $\theta_q(x_{q+1}, x_{q+4}) = 1$. Let f be an embedding of K_7 in S^3 . Then it is not hard to check that:

$$3\tilde{\mathcal{L}}_{\varepsilon}(f) = \sum_{q=1}^{7} \tilde{\mathcal{L}}_{\varepsilon_{q}}(f|_{G_{q}}) + \sum_{q=1}^{7} \tilde{\mathcal{L}}_{\zeta_{q}}(f|_{H_{q}}) + \sum_{q=1}^{7} \tilde{\mathcal{L}}_{\eta_{q}}(f|_{F_{q}}) - 5\sum_{q=1}^{7} \tilde{\mathcal{L}}_{\theta_{q}}(f|_{J_{q}}).$$

5. Minimal crossing number of a spatial graph

Let f be a spatial embedding of a graph G. The following theorem gives a lower bound for the minimal crossing number of any projection of f up to isotopy.

THEOREM 5.1. Let f be an embedding of an oriented graph G in S^3 with generalized Simon invariant $\hat{L}_{\varepsilon}(f)$, and let c(f) be the minimum crossing number of all projections of all embeddings ambient isotopic to f. Let m_{ε} be the maximum of $|\varepsilon(e_i, e_j)|$ over all pairs of disjoint edges in G. Then

$$\left|\widehat{L}(f)\right| \leq c(f)m_{\varepsilon}.$$

Proof. Fix a diagram of f(G) which realizes the minimal crossing number c(f). Observe that c(f) includes crossings between an edge and itself as well as crossings between adjacent edges, which are not included in $\sum_{e_i \cap e_j = \emptyset} |\ell(f(e_i), f(e_j))|$. Therefore, we have the following sequence of inequalities.

$$\begin{aligned} |\widehat{L}_{\varepsilon}(f)| &= \left| \sum_{e_i \cap e_j = \varnothing} \varepsilon(e_i, e_j) \ell(f(e_i), f(e_j)) \right| \\ &\leqslant \sum_{e_i \cap e_j = \varnothing} |\varepsilon(e_i, e_j)| |\ell(f(e_i), f(e_j))| \\ &\leqslant m_{\varepsilon} \sum_{e_i \cap e_j = \varnothing} |\ell(f(e_i), f(e_j))| \\ &\leqslant m_{\varepsilon} c(f). \end{aligned}$$

Fig. 18. This projection of an embedded K_6 has a minimal number of crossings.

Thus we have the result.

Since every reduced Wu invariant with respect to a given homomorphism ε is a generalized Simon invariant with epsilon coefficients given by $\varepsilon(a, b)$, Theorem 5.1 is true for any reduced Wu invariant $\tilde{\mathcal{L}}_{\varepsilon}(f)$.

Recall from Example 2.7 that the reduced Wu invariant of $2K_3$ is twice the linking number. Thus applying Theorem 5.1 to an embedding of $2K_3$ gives us the well known fact that the minimal crossing number of a 2-component link is at least twice the absolute value of the linking number. Applying Theorem 5.1 to Examples 2.2 and 2.3 shows that the minimal crossing number of any spatial embedding of K_5 or $K_{3,3}$ is at least the absolute value of the Simon invariant.

Example 5.2. Let f be a spatial embedding of K_7 . Consider the generalized Simon invariant $\widehat{L}_{\varepsilon}(f)$ given in Section 3. Since $m_{\varepsilon}(f) = 1$ for any projection of f, it follows from Theorem 5.1 that $c(f) \ge |\widehat{L}_{\varepsilon}(f)|$.

Example 5.3. Consider the oriented and labelled K_6 illustrated in Figure 16. We introduce a new generalized Simon invariant for K_6 where the epsilon coefficients are given by:

$$\varepsilon(x_i, x_j) = \varepsilon(z_i, z_j) = 1$$

$$\varepsilon(y_i, y_j) = \varepsilon(x_i, z_j) = -1$$

$$\varepsilon(x_i, y_j) = \varepsilon(y_i, z_j) = 0.$$

It is not hard to check that these epsilon coefficients indeed give us a generalized Simon invariant for K_6 . Alternatively, if we let T_1 be the triangle with vertices y_1 , y_2 , and y_3 and let T_2 be the triangle with vertices y_4 , y_5 , and y_6 , then we can define $\tilde{\mathcal{L}}_{\varepsilon}(f)$ as the sum of $2\text{lk}(f(T_1), f(T_2))$ together with the Simon invariant of the oriented $K_{3,3}$ -subgraph obtained from K_6 by deleting T_1 and T_2 .

Let f be the spatial embedding of K_6 illustrated in Figure 18, where 2n + 1 is the number of positive crossings. We compute the generalized Simon invariant $\tilde{\mathcal{L}}_{\varepsilon}(f)$ as:

$$\tilde{\mathcal{L}}_{\varepsilon}(f) = \varepsilon(y_1, y_4) \cdot (2n+1) + \varepsilon(x_4, z_2) \cdot 1 + \varepsilon(y_6, y_3) \cdot 1 = -(2n+1) - 1 = -2n - 3.$$

Since $m_{\varepsilon} = 1$, it follows from Theorem 5.1 that $c(f) \ge |\widehat{L}_{\varepsilon}(f)| = 2n+3$. The projection in Figure 18 has 2n + 3 crossings. Thus this projection has a minimal number of crossings. In particular, this means that for every odd number $k \ge 3$, there is an embedding g of K_6 in S^3 such that c(g) = k.

Example 5.4. Let f be the embedding of the Heawood graph illustrated in Figure 19, where the numbers in each of the rectangles is the number of positive crossings. Using the

Fig. 19. This projection of an embedded Heawood graph has a minimal number of crossings.

generalized Simon invariant from Section 3, we find that $\widehat{L}_{\varepsilon}(f) = 5(2k+1) + 5(2m+1) + 5(2n+1)$. Also, $m_{\varepsilon} = 5$. Now it follows from Theorem 5.1 that $c(f) \ge 2(k+m+n) + 3$. Since this is precisely the number of crossings in Figure 19, it follows that this projection has a minimal number of crossings. Since we can choose any values for k, m, and n, it follows that for every odd number $l \ge 3$, there is an an embedding g of the Heawood graph in S^3 such that c(g) = l.

Acknowledgements. The authors are grateful to Professor Kouki Taniyama for suggesting that the Wu invariant might be used to obtain bounds on the minimal crossing number of a spatial graph.
